DRABA MAGUIREI* SUBSP. *STONEI

Scientific name: *Draba maguirei* C. L. Hitchc. subsp. *stonei* Windham
(common name) Stone's draba

Family: Brassicaceae
(common name) Mustard family

Synonyms:
None; published in March of 2023

Global Distribution:
Endemic to Cache County, Utah

Land Ownership:
FS - Wasatch-Cache NF

Habitat:
Maple/oak and Douglas-fir communities on dolomite, between 5,500 and 7,000 feet elevation, May - early June.

Comments:
This subspecies differs from subsp. *maguirei* by having mostly bifurcate trichomes covering entire leaf rather than cruciform trichomes confined to leaf margins, and flowering stems with at least some branched trichomes as opposed to glabrous stems. It also grows at lower elevations and has an earlier flowering time than subsp. *maguirei*. The two subspecies also have different ploidy levels and do not co-occur. Its branched trichomes that cover the leaf also differ from the unbranched ones confined to leaf margins of *D. burkei*.
